

TURBOMACHINERY: COMPRESSOR PRELIMINARY DESIGN

Antonio Pucciarelli

Politecnico di Milano

September 24, 2022

1 Problem Description

2 Mean Line

3 Models

4 turboLIB & Results

Initial conditions & constraints

Inlet conditions

- $P_{T0} = 1\text{bar}$
- $T_{T0} = 300\text{K}$

Constraints

- $r_{max} = 0.45\text{m}$
- $\beta_{TT} = 1.45$
- $\dot{m} = 100 \frac{\text{kg}}{\text{s}}$
- $\max \eta$

Due to the **course track** and **preference**, the turbomachinery design will be on an **axial** compressor.

1 Problem Description

4 turboLIB & Results

1 Problem Description

2 Mean Line

Problem setup

Main design quantities

V_{tmean} , V_{amean} , U_{mean} & velocity triangles

3 Models

4 turboLIB & Results

Problem setup: hypothesis

Hypothesis

- **not using** an **inlet guide vane** for simplicity of design
- keeping, in the similarity/adimensional analysis of the compressor, $V_{a_{mean}}$ **constant**¹
- keeping the blade height, b_0 , **constant** both in rotor and stator
- using a **mixed vortex** model for the **rotor** velocity triangles
- using a **second order** function for the **stator** velocity triangles
- neglecting inlet **entropy** generation and assuming **rotor inlet** quantities **constant**
- **shrouding** at blade tip not present
- **rotor-stator** losses neglected

¹ \dot{m} corrections will be made later on in the **radial equilibrium** solution.

Problem setup: solution steps

Main procedural steps:

- λ and ψ computation from χ and V_{t0}
- ϕ and η computation
- $V_{a_{mean}}$ and L_{eu} computation from ϕ , β_{TT} and η
- computing **mean** velocity triangles, using the above hypothesis
- computing **mean thermodynamic** quantities
- computing **blade height**

1 Problem Description

2 Mean Line

Problem setup

Main design quantities

V_{tmean} , V_{amean} , U_{mean} & velocity triangles

3 Models

4 turboLIB & Results

Graph analysis: χ & r_{mean}

$$\chi = 0.58, r_{mean} = 0.32$$

$$\eta = 0.906$$

$$\Delta\beta = -36.63^\circ$$

$$\omega = 658.25 \frac{rad}{s}, rpm = 6286$$

$$\Delta\alpha_{stator} = 41.07^\circ$$

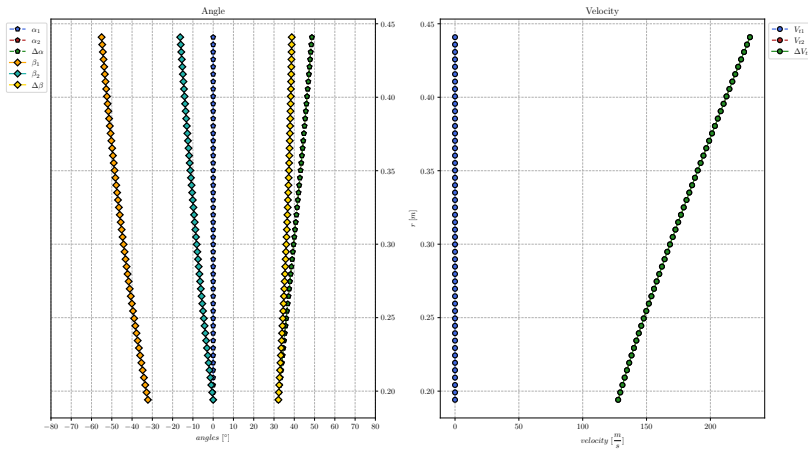

$$r_{tip} = 0.446m, b_0 = 0.252m$$

$$M_r = 0.87$$

Graph analysis: **rotor** α , β & V_t

Graph analysis: stator α & V_t

λ & ψ

From the previous **graphs**:

- $^2\chi = 0.58$
- $r_{mean} = 0.32m$
- $\frac{V_{t0}}{U_{mean}} = 0$

Taking into account the previous modeling **hypothesis**:

$$\lambda = \left(1 - \chi - \frac{V_{t0}}{U_{mean}} \right) \cdot 4$$

$$\psi = \frac{\lambda}{2}$$

$$^2\chi = \frac{h_1 - h_0}{h_{T1} - h_{T0}} = \frac{\frac{w_0^2}{2} - \frac{w_1^2}{2}}{U_{mean}(V_{t1} - V_{t0})} = \frac{\frac{w_{a0}^2}{2} + \frac{w_{t0}^2}{2} - \frac{w_{a1}^2}{2} - \frac{w_{t1}^2}{2}}{U_{mean}(V_{t1} - V_{t0})} = \frac{\frac{w_{t0}^2}{2} - \frac{w_{t1}^2}{2}}{U_{mean}(V_{t1} - V_{t0})}$$

$$\phi(\psi)$$

From [Aun04, Sec. 10.4] it is imposed that $\frac{W_2}{W_1} \geq 0.7$ with a *safety* margin of 3%. ϕ_{lim} line is related to the **surge safety margin**.

η & L_{eu}

η is computed from an **Lieblein** efficiency chart³ given ϕ and χ . This parameter will be used for the computation of L_{eu} given the β_{TT} target.

$$L_{is} = \frac{\gamma R}{\gamma - 1} T_{T0} (\beta_{TT}^{\frac{\gamma-1}{\gamma}} - 1)$$

$$L_{eu} = \frac{L_{is}}{\eta}$$

³This chart has been interpolated from the course slides charts.

Profile losses

The profile losses used are related to the **Leiblein modeling** approach⁶.

The model is based on the **equivalent diffusion factor**⁷, D_{eq} :

$$\frac{W_{max}}{W_1} = 1.12 + 0.61 \frac{\cos(\beta_1)^2}{\sigma} \cdot \frac{r_1 V_{t1} - r_2 V_{t2}}{r_1 V_{a1}}$$

$$D_{eq} = \frac{W_{max}}{W_1} \cdot \frac{W_1}{W_2}$$

D_{eq} will be used for the computation of $\bar{\omega}_{profile}$ as:

$$\bar{\omega}_{profile} = \frac{0.004 \left(1 + 3.1 (D_{eq} - 1)^2 + 0.4 (D_{eq} - 1)^8 \right) 2 \sigma}{\cos(\beta_2) \left(\frac{W_1}{W_2} \right)^2}$$

⁶The following equations are interpolated data from [Aun04, Sec. 6.4].

⁷It describes how important is the **velocity change** along the blade. It can be seen as an *indicator* of the **blade loading**.

Compressibility losses – I

These losses can be seen as a **correction** of the **profile** losses due to the compressibility of the gas along its *journey* in the stage.

The correction refers to a **Leiblein correction** model that uses the **positive** and **negative** blade section incidence angle⁸, i_c and i_s .

These new stall incidence angles will build a new **mean** incidence angle, i_m , that can be seen as the **optimum** incidence angle related to the inlet Mach conditions⁹.

⁸ i_c and i_s are related to the total pressure losses, $\bar{\omega}_c$ and $\bar{\omega}_s$, that are **twice** the minimum total pressure loss, $\bar{\omega}$, obtained at the **design incidence angle**, i^* .

⁹The implemented model follows [Aun04, Sec. 6.6]

Compressibility losses – II

$\bar{\omega}_{compressibility}$ setup:

- R_c and R_s computation¹⁰:

$$R_c = 9 - \left[1 - \left(\frac{30}{\beta_1} \right)^{0.48} \right] \frac{\theta}{8.2}$$

$$R_s = 10.3 + \left(2.92 - \frac{\beta_1}{15.6} \right) \frac{\theta}{8.2}$$

- i_c and i_s computation due to **compressibility** effects:

$$i_c = i^* - \frac{R_c}{1 + 0.5 M_1^3}$$

$$i_s = i^* + \frac{R_s}{1 + 0.5 (K_{sh} M_1)^3}$$

¹⁰ R_c and R_s are **range indices** for the computation of i_c and i_s .

Compressibility losses – III

- i_m computation¹¹: $i_m = i_c + (i_s - i_c) \frac{R_c}{R_c + R_s}$
- $\bar{\omega}_m$ computation: $\bar{\omega}_m = \bar{\omega}_{profile} \left[1 + \frac{(i_m - i^*)^2}{R_s^2} \right]$
- $\bar{\omega}_{compressibility}$ computation¹²:

$$\bar{\omega}_{compressibility} = \bar{\omega}_m + \bar{\omega}_m \left[\frac{i - i_m}{i_c - i_m} \right]^2, \text{ if } i \leq i_m$$

$$\bar{\omega}_{compressibility} = \bar{\omega}_m + \bar{\omega}_m \left[\frac{i - i_m}{i_s - i_m} \right]^2, \text{ if } i \geq i_m$$

¹¹ i_m is the incidence angle at which corresponds, having accounted the **compressibility**, the **minimum pressure loss**, $\bar{\omega}_m$.

¹²After having computed i_c , i_s , i_m and $\bar{\omega}_m$. $\bar{\omega}_{compressibility}$ is a function of i . In the **total pressure losses study**: $\bar{\omega}_{compressibility} = \bar{\omega}_{compressibility(i^*)}$.

Secondary flow losses

These losses are relative to the **secondary flow** inside the compressor and are *usually* **greater** than the other losses. These losses are related to **eddies** generated with the **blade-flow** interaction and **streamlines** displacement due to the presence of **pressure gradients**.

These losses are computed with **Howell's** model [Aun04, Ch. 6]¹³:

$$\bar{\beta} = \frac{\arctan(\tan(\beta_1) + \tan(\beta_2))}{2}; \quad \text{I}$$

$$C_L = 2 \cos(\bar{\beta}) \cdot \frac{\tan(\beta_1) - \tan(\beta_2)}{\sigma}; \quad \text{II}$$

$$C_D = 0.18 C_L^2; \quad \text{III}$$

$$\bar{\omega}_{secondary} = C_D \sigma \cdot \frac{\cos(\beta_1)^2}{\cos(\bar{\beta})^3}; \quad \text{loss computation}$$

¹³Howell computed a secondary flow loss model that is automatically embedded into $\bar{\omega}_{profile}$: this model is used for the **estimation** of the stator/rotor

End wall losses

These losses are related the interaction between the flow and the **compressor case**. They are *lower* than the **secondary flow** losses. It has been used a simple and fast relation made by **Howell** [Aun04, Ch. 6]¹⁴:

$$C_D = 0.02 \frac{s}{b_0}$$
$$\bar{\omega}_{endWall} = C_D \sigma \cdot \frac{\cos(\beta_1)^2}{\cos(\bar{\beta})^3}; \quad \text{loss computation}$$

¹⁴This loss is kept into account in the **blade numbering** study.

Shock losses – I

The **relative** Mach number at the rotor inlet is slightly above **sonic speed**; a **shock wave** will be present at the rotor tip. From [MF20], **shock pattern** is related to **Mach number** and **airfoil shape**.

The **shock** losses modeling is related to **König losses** modeling approach. This model describes a **2 shock waves loss** using a **single normal shock** with respect to a computed Mach number, M_{in} .

König model depends mainly on **blade deflection angle**, θ , and **relative inlet Mach**¹⁵, M_1 .

¹⁵ **Leading edge radius** is not taken into account due to the *approximated nature* of the model.

Shock losses – II

Swan and **Miller**, [Aun04, Sec. 6.7], derived a **shock loss formulation** from **König model**.

The following are the steps made for the computation of the **shock loss**, $\bar{\omega}_{shock}$, at each **blade section**:

- computation of the **expansion wave** angle, ϕ :

$$\phi = \frac{s \cos(\psi)}{s \sin(\psi) R_u}; \text{ where } \psi = \psi(\beta_1, \gamma, \theta)$$

- computation of W_s and M_s using **Prandtl-Meyer** expansion:

$$\phi = \int_{W_1}^{W_s} \sqrt{M^2 - 1} \frac{dW}{W}$$

- M_{in} computation: $M_{in} = \sqrt{M_1 M_s}$
- **normal shock** solution and computation of ΔP_T
- from ΔP_T , computation of $\bar{\omega}_{shock}$

Tip leakage losses

Again these losses are computed from [Aun04, Sec. 6.9]. The main concept is: computing a **total** blade pressure loss and **assuming linear distribution** of losses from the hub to the tip¹⁶.

$$\tau = \pi \delta_c \left[r_1 \rho_1 V_{a1_{mean}} + r_2 \rho_2 V_{a2_{mean}} \right] \left[r_2 V_{t2_{mean}} - r_1 V_{t1_{mean}} \right]$$

$$\Delta P = \frac{\tau}{Z r_{tip} \delta_c c \cos(\gamma)}$$

$$U_c = 0.816 \frac{\sqrt{\frac{2\Delta P}{\rho_{mean}}}}{N_{row}^{0.2}}$$

$$\dot{m}_c = \rho_{mean} U_c Z \delta_c c \cos(\gamma)$$

$$\Delta P_T = \frac{\Delta P \dot{m}_c}{\dot{m}}$$

ΔP_T is the **overall** total pressure loss due to **tip leakage**.

¹⁶ Z is the number of blades. δ_c is the tip clearance. N_{row} is the number of blade rows in the compressor.

2 Mean Line

3 Models

Losses modeling

Blade shape

Radial equilibrium

4 turboLIB & Results

Blade shape setup

The **Leiblein model** from [Aun04, Ch. 6] has been used for the blade shape computation.

NACA – 65 profile has been chosen for the blade generation¹⁷.

The **main constraints** are: $\frac{t_b}{c} \approx 0.1$ and σ is related just to s ¹⁸.

Due to the many possible blade configurations, an **optimization** procedure has been used for the computation of i^* , δ and θ .

Each section airfoil shape is **computed** from θ and NACA – 65 C_{L0} surface coordinates.

¹⁷Due to the low tip sonic Mach number it has been chosen to use this profile as well for the blade tip instead of a supersonic adapted profile shape.

¹⁸ $\frac{t_b}{c} \approx 0.1$ allows setting $K_{sh} \approx 0.1$. The blade chord, c , is set up as constant during the **blade numbering** study: using $AR = \frac{b_0}{c}$.

i^* computation

The **incidence angle**, i^* , is computed using:

$$K_{t,i} = \left(10 \frac{t_b}{c} \right)^q ; \text{ where } q = \frac{0.28}{0.1 + \left(\frac{t_b}{c} \right)^{0.3}}$$

$$(i_0^*)_{10} = \frac{\beta_0^p}{5 + 46 \cdot e^{-2.3\sigma}} - 0.1 \sigma^3 e^{\frac{\beta_0 - 70}{4}} ; \text{ where } p = 0.914 + \frac{\sigma^3}{160}$$

$$n = 0.025\sigma - 0.06 - \frac{\left(\frac{\beta_0}{90} \right)^{1+1.2\sigma}}{1.5 + 0.43\sigma}$$

$$i^* = K_{sh} K_{t,i} (i_0^*)_{10} + n \theta$$

δ computation

The **deviation angle**, δ , is computed using:

$$K_{t,\delta} = 6.25 \frac{t_b}{c} + 37.5 \left(\frac{t_b}{c} \right)^2$$

$$(\delta_0^*)_{10} = 0.01\sigma\beta_0 + (0.74\sigma^{1.9} + 3\sigma) \left(\frac{\beta_0}{90} \right)^{1.67+1.09\sigma}$$

$$b = 0.9625 - 0.17 \frac{\beta_0}{100} - 0.85 \left(\frac{\beta_0}{100} \right)^3$$

$$m = \frac{m_{1.0}}{\sigma^b} ; \text{ where } m_{1.0} = 0.17 - 0.0333 \frac{\beta_0}{100} + 0.333 \left(\frac{\beta_0}{100} \right)^2$$

$$\delta = K_{sh} K_{t,\delta} (\delta_0^*)_{10} + m \theta$$

θ computation

Starting from the **known** flow deflection angle¹⁹, ε , it is necessary to compute:

$$\theta = \varepsilon - i^* + \delta$$

Since i^* and δ are functions of θ , the computation of θ is made by an **iterative process**:

$$\theta = \varepsilon - i_{(\theta)}^* + \delta_{(\theta)}$$

Once found θ , the **total pressure loss** coefficients, $\bar{\omega}_*$, are computed.

¹⁹ $\varepsilon = \beta_{inlet} - \beta_{outlet}$. β_1 and β_2 change with respect to the **axial speed**.

1 Problem Description

2 Mean Line

3 Models

Losses modeling

Blade shape

Radial equilibrium

4 turboLIB & Results

Equation setup

The **radial equilibrium** equation: $\frac{\partial h_t}{\partial r} = T \frac{\partial s}{\partial r} + V_a \frac{\partial V_a}{\partial r} + V_t \frac{\partial V_t}{\partial r}$ is converted into, for the exit station²⁰ of the blade, a **1st order ODE**:

$$-\frac{1}{2} \frac{\partial V_{a2}^2}{\partial r} + \frac{V_{a2}^2}{2 c_p} \frac{\partial s_2}{\partial r} = -c_p \frac{\partial T_{T1}}{\partial r} - \omega \frac{\partial r V_{t2}}{\partial r} + \omega \frac{\partial r V_{t1}}{\partial r} + T_{T1} \frac{\partial s_2}{\partial r} + \frac{\omega}{c_p} r V_{t2} \frac{\partial s_2}{\partial r} - \frac{\omega}{c_p} r V_{t1} \frac{\partial s_2}{\partial r} - \frac{1}{2 c_p} V_{t2}^2 \frac{\partial s_2}{\partial r} + \frac{V_{t2}}{r} \frac{\partial r V_{t2}}{\partial r}$$

- The **ODE** will be solved for V_{a2}^2
- s_2 is computed from²¹ $\sum_i \bar{\omega}_i$.
- ω , V_{t1} , V_{t2} and T_{T1} are known

²⁰1 is the blade inlet station and 2 is the blade outlet section.

²¹ $\bar{\omega}_*$ computation has been treated earlier in [Losses modeling](#).

Δs computation

From pressure loss coefficients it is possible compute the **outlet total pressure** as:

$$P_{T2,r} = P_{T1,r} + \sum_i \bar{\omega}_i (P_{T1,r} - P_{1,r})$$

The **entropy variation** is computed as:

$$\Delta s = s_2 - s_1 = c_p \log \frac{T_{T2,r}}{T_{T1,r}} - R \log \frac{P_{T2,r}}{P_{T1,r}}$$

Frames

- $T_{T2} = T_{T1}$ in **stators** and $T_{T2,r} = T_{T1,r}$ in **rotors**
- $\bar{\omega}_*$ have to be computed using **relative** quantities for **rotors** and **absolute** quantities for **stators**
- $T_{T,r} = T + \frac{W^2}{2c_p} = T_T + \frac{W^2 - V^2}{2c_p}$
- $P_{T,r} = P_T \left(\frac{T_{T,r}}{T_T} \right)^{\frac{\gamma}{\gamma-1}}$

Results

turboLIB

The preliminary compressor design model program **turboLIB** can be downloaded from GitHub.

Main objects and modules

- `turboClass.turboBlade.blade`: blade object
- `turboCoeff`: engineering coefficients module
 - `losses`: losses modeling
 - `similarity`: adimensional analysis
 - `lieblein`: blade modeling
- `geometry.bladeGeometry.geometryData`: airfoil object

Blade number

In order to define a proper number of blades for the rotor and the stator, **Howell's** relations have been used for the estimation of the **losses**. These relations, [Aun04, Ch. 6], are:

- $\bar{\omega}_{profile+secondary}$, this is a relation that takes into account **profile** and **3D** losses
- $\bar{\omega}_{endWall}$, this is previous expalined **end wall** loss

Rotor

Stator

NISRE

The NISRE is solved through a **double nested** loop:

- **continuity loop.** Inside the **continuity loop** the `scipy.integrate.odeint` function is used for the solution of the V_{a2}^2 **ODE**.
- **entropy loop.** Inside the **entropy loop** the `scipy.optimize.minimize` function is used for the computation of the blade **shape**.

.stl & .scad generation

At the end of the NISRE, all the main blade quantities are available for the **generation** of the **3D geometry**. This geometry can be converted into a .stl file that can be used in OpenFOAM for the flow properties study. In addition a .scad file is made for understanding position and checking possible contacts between rotor and stator blades.

[Bas06] suggested that a good distance between rotor and stator blades is half of the rotor chord²².

²²In the radial equilibrium study losses between rotor and stator blades are **neglected**.
