Initial conditions & constraints

Inlet conditions

- $P_{T0} = 1bar$
- $T_{T0} = 300K$

Constraints

- $r_{max} = 0.45m$
- $\beta_{TT} = 1.45$
- $\dot{m} = 100 \frac{kg}{s}$
- max η

Due to the **course track** and **preference**, the turbomachinery design will be on an **axial** compressor.

2 Mean Line

Problem setup Main design quantities $V_{t_{mean}}$, $V_{a_{mean}}$, U_{mean} & velocity triangles

Main design quantities

Mean Line

0.0000000000

 $V_{t_{mean}}$, $V_{a_{mean}}$, U_{mean} & velocity triangles

- 3 Models
- 4 turboLIB & Results

Problem setup: hypothesis

Hypothesis

- not using an inlet guide vane for simplicity of design
- keeping, in the similarity/adimensional analysis of the compressor, $V_{a_{mean}}$ constant¹
- keeping the blade height, b_0 , **constant** both in rotor and stator
- using a mixed vortex model for the rotor velocity triangles
- using a second order function for the stator velocity triangles
- neglecting inlet entropy generation and assuming rotor inlet quantities constant
- shrouding at blade tip not present
- rotor-stator losses neglected

 $^{^{1}\}dot{m}$ corrections will be made later on in the **radial equilibrium** solution.

Main procedural steps:

- λ and ψ computation from χ and V_{t0}
- ϕ and η computation
- $V_{a_{mean}}$ and L_{eu} computation from ϕ , eta_{TT} and η
- computing mean velocity triangles, using the above hypothesis
- computing mean thermodynamic quantities
- computing blade height

- 1 Problem Description
- 2 Mean Line

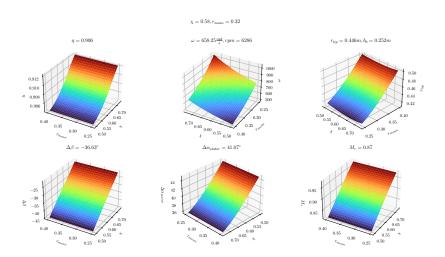

Problem setup

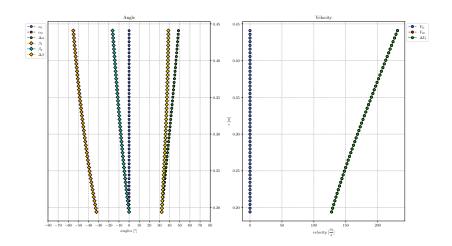

Main design quantities

 $V_{t_{mean}}$, $V_{a_{mean}}$, U_{mean} & velocity triangles

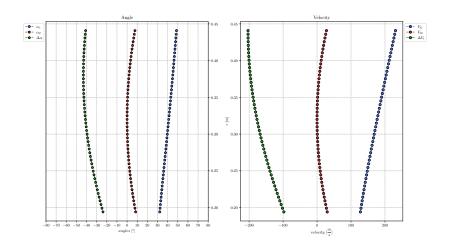

- 3 Models
- 4 turboLIB & Results

Graph analysis: **stator** $\alpha \& V_t$

From the previous **graphs**:

- $\chi = 0.58$
- $r_{mean} = 0.32m$
- $\frac{V_{t0}}{U_{mean}} = 0$

Taking into account the previous modeling **hypothesis**:

$$\lambda = \left(1 - \chi - rac{V_{t0}}{U_{mean}}
ight) \cdot 4$$
 $\psi = rac{\lambda}{2} = rac{L_{eu_{mean}}}{U_{mean}^2}$

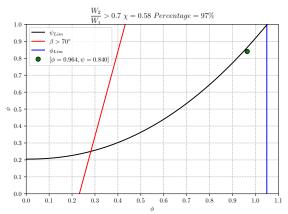

$$\chi = \frac{h_1 - h_0}{h_{T1} - h_{T0}} = \frac{\frac{W_0^2}{2} - \frac{W_1^2}{2}}{U_{mean}(V_{t1} - V_{t0})} = \frac{\frac{W_0^2}{2} + \frac{W_1^2}{20} - \frac{W_1^2}{21} - \frac{W_1^2}{2}}{U_{mean}(V_{t1} - V_{t0})} = \frac{\frac{W_0^2}{10} - \frac{W_1^2}{12}}{U_{mean}(V_{t1} - V_{t0})}.$$

Politecnico di Milano

Antonio Pucciarelli

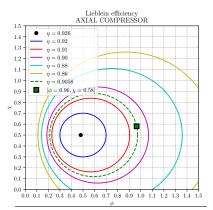

From [Aun04, Sec. 10.4] it is imposed that $\frac{W_2}{W_1} \ge 0.7$ with a *safety* margin of 3%. ϕ_{lim} line is related to the **surge safety margin**.

 $\phi = \frac{V_{a_{mean}}}{U_{mean}}$

POLITECNICO MILANO 1863

 η is computed from an **Lieblein** efficiency chart² given ϕ and χ . This parameter will be used for the computation of L_{eu} given the β_{TT} target.

$$egin{align} L_{is} &= rac{\gamma}{\gamma} rac{R}{T} \ T_{\mathcal{T}0} \ (eta_{TT}^{rac{\gamma-1}{\gamma}} - 1) \ L_{eu} &= rac{L_{is}}{\eta} \ \end{array}$$

Losses modeling

Antonio Pucciarelli

Politecnico di Milano

The profile losses used are related to the **Leiblein modeling** approach⁵.

The model is based on the equivalent diffusion factor⁶, D_{eq} :

$$\begin{split} \frac{W_{max}}{W_1} &= 1.12 + 0.61 \ \frac{\cos(\beta_1)^2}{\sigma} \cdot \frac{r_1 \ V_{t1} - r_2 \ V_{t2}}{r_1 \ V_{a1}} \\ D_{eq} &= \frac{W_{max}}{W_1} \cdot \frac{W_1}{W_2} \end{split}$$

 D_{eq} will be used for the computation of $\bar{\omega}_{profile}$ as:

$$\bar{\omega}_{\textit{profile}} = \frac{0.004\,\left(1 + 3.1\,\left(D_{\textit{eq}} - 1\right)^2 + 0.4\,\left(D_{\textit{eq}} - 1\right)^8\right)\,2\,\,\sigma}{\cos(\beta_2)\,\left(\frac{W_1}{W_2}\right)^2}$$

⁵The following equations are interpolated data from [Aun04, Sec. 6.4].

⁶It describes how important is the **velocity change** along the blade. It can be seen as an *indicator* of the **blade loading**.

These losses can be seen as a **correction** of the **profile** losses due to the compressibility of the gas along its *journey* in the stage.

The correction refers to a Leiblein correction model that uses the **positive** and **negative** blade section incidence angle⁷, i_c and i_s .

These new stall incidence angles will build a new mean incidence angle, i_m , that can be seen as the **optimum** incidence angle related to the inlet Mach conditions⁸.

⁸The implemented model follows [Aun04, Sec. 6.6].

 $^{^7}i_c$ and i_s are related to the total pressure losses, $\bar{\omega}_c$ and $\bar{\omega}_s$, that are **twice** the minimum total pressure loss, $\bar{\omega}$, obtained at the **design incidence angle**, i^* .

 $\bar{\omega}_{compressibility}$ setup:

• R_c and R_s computation⁹:

$$R_c = 9 - \left[1 - \left(\frac{30}{\beta_1}\right)^{0.48}\right] \frac{\theta}{8.2}$$

$$R_s = 10.3 + \left(2.92 - \frac{\beta_1}{15.6}\right) \frac{\theta}{8.2}$$

• i_c and i_s computation due to **compressibility** effects:

$$i_c = i^* - \frac{R_c}{1 + 0.5 M_1^3}$$
 $i_s = i^* + \frac{R_s}{1 + 0.5 (K_{sh} M_1)^3}$

 $^{{}^{9}}R_{c}$ and R_{s} are range indices for the computation of i_{c} and i_{s} .

- i_m computation¹⁰: $i_m = i_c + (i_s i_c) \frac{R_c}{R_c + R_c}$
- $\bar{\omega}_m$ computation: $\bar{\omega}_m = \bar{\omega}_{profile} \left[1 + \frac{\left(i_m i^*\right)^2}{R_s^2} \right]$
- $\bar{\omega}_{compressibility}$ computation¹¹:

$$\bar{\omega}_{compressibility} = \bar{\omega}_m + \bar{\omega}_m \left[\frac{i - i_m}{i_c - i_m} \right]^2, \text{ if } i \leq i_m$$

$$\bar{\omega}_{compressibility} = \bar{\omega}_m + \bar{\omega}_m \left[\frac{i - i_m}{i_s - i_m} \right]^2, \text{ if } i \geq i_m$$

 $^{^{10}}i_{m}$ is the incidence angle at wich corresponds, having accounted the compressibility, the minimum pressure loss, $\bar{\omega}_m$.

¹¹After having computed i_c , i_s , i_m and $\bar{\omega}_m$. $\bar{\omega}_{compressibility}$ is a function of i. In the total pressure losses study: $\bar{\omega}_{compressibility} = \bar{\omega}_{compressibility_{(i*)}}$.

Secondary flow losses

These losses are relative to the **secondary flow** inside the compressor and are usually greater than the other losses. These losses are related to eddies generated with the blade-flow interaction and streamlines displacement due to the presence of pressure gradients.

These losses are computed with **Howell**'s model [Aun04, Ch. 6]¹²:

$$\bar{\beta} = \frac{\arctan(\tan(\beta_1) + \tan(\beta_2))}{2};$$

$$-\tan(\beta_1) - \tan(\beta_2)$$

$$C_L = 2 \cos(\bar{\beta}) \cdot \frac{\tan(\beta_1) - \tan(\beta_2)}{\sigma};$$

$$C_D = 0.18 \ C_L^2;$$

$$\bar{\omega}_{secondary} = C_D \ \sigma \cdot \frac{\cos(\beta_1)^2}{\cos(\bar{\beta})^3};$$
 loss computation

¹²Howell computed a secondary flow loss model that is automatically embedded into $\bar{\omega}_{profile}$. It is used for the **estimation** of the **blade number**.

These losses are related the interaction between the flow and the **compressor case**. They are *lower* than the **secondary flow** losses. It has been used a simple and fast relation made by **Howell** [Aun04, Ch. 6]¹³:

$$C_D=0.02~rac{s}{b_0}$$

$$ar{\omega}_{endWall}=C_D~\sigma\cdotrac{cos(eta_1)^2}{cos(ar{eta})^3}; \qquad \qquad ext{loss computation}$$

¹³This loss is kept into account in the **blade numbering** study.

Shock losses – L

The **relative** Mach number at the rotor inlet is slightly above **sonic speed**; a **shock wave** will be present at the rotor tip. From [MF20], shock pattern is related to Mach number and airfoil shape.

The **shock** losses modeling is related to **König losses** modeling approach. This model describes a 2 shock waves loss 14 using a single normal shock with respect to a computed Mach number, M_{in} .

König model depends mainly on **blade deflection angle**, θ , and relative inlet Mach¹⁵. M_{1} .

¹⁵Leading edge radius is not taken into account due to the approximated nature of the model.

¹⁴For a flow in **unstarted condition**: shock wave *followed by* an expansion wave and another shock wave. Unstarted conditions are for $M_{a,r} < 1$.

Swan and Miller, [Aun04, Sec. 6.7], derived a shock loss formulation from König model.

The following are the steps made for the computation of the **shock** loss, $\bar{\omega}_{shock}$, at each blade section:

• computation of the **expansion wave** angle, ϕ :

$$\phi = \frac{s \cos(\psi)}{s \sin(\psi) R_u}; \text{ where } \psi = \psi_{(\beta_1, \ \gamma, \ \theta)}$$

computation of W_s and M_s using **Prandtl-Meyer** expansion:

$$\phi = \int_{W_1}^{W_s} \sqrt{M^2 - 1} \; \frac{dW}{W}$$

- M_{in} computation: $M_{in} = \sqrt{M_{1,r} M_s}$
- normal shock solution and computation of ΔP_T
- from ΔP_T , computation of $\bar{\omega}_{shock}$

Again these losses are computed from [Aun04, Sec. 6.9]. The main concept is: computing a **total** blade pressure loss and **assuming linear distribution** of losses from the hub to the tip¹⁶.

$$\begin{split} \tau &= \pi \ \delta_c \left[r_1 \rho_1 V_{a1_{mean}} + r_2 \rho_2 V_{a2_{mean}} \right] \left[r_2 V_{t2_{mean}} - r_1 V_{t1_{mean}} \right] \\ \Delta P &= \frac{\tau}{Z \ r_{tip} \delta_c \ c \ cos(\gamma)} \\ U_c &= 0.816 \frac{\sqrt{\frac{2\Delta P}{\rho_{mean}}}}{N_{row}^{0.2}} \\ \dot{m_c} &= \rho_{mean} \ U_c \ Z \ \delta_c \ c \ cos(\gamma) \\ \Delta P_T &= \frac{\Delta P \ \dot{m_c}}{\dot{m}} \end{split}$$

 ΔP_T is the **overall** total pressure loss due to **tip leackage**.

 $^{^{16}}Z$ is the number of blades. δ_c is the tip clearance. \textit{N}_{row} is the number of blade rows in the compressor.

Antonio Pucciarelli

Politecnico di Milano

The **Leiblein model** from [Aun04, Ch. 6] has been used for the blade shape computation.

 ${\tt NACA-65}$ profile has been chosen for the blade generation ${\tt 17}$.

The **main contraints** are: $\frac{t_b}{c} \approx 0.1$ and σ is related just to s^{18} .

Due to the many possible blade configurations, an **optimization** procedure has been used for the computation of i^* , δ and θ .

Each section airfoil shape is **computed** from θ and NACA - 65 C_{L0} surface coordinates.

¹⁷Due to the low tip sonic Mach number it has been chosen to use this profile as well for the blade tip instead of a supersonic adapted profile shape.

 $[\]frac{^{18}\frac{t_b}{c}}{\approx} \approx 0.1$ allows setting $K_{sh} \approx 0.1$. The blade chord, c, is set up as constant during the **blade numbering** study: using $AR = \frac{b_0}{c}$.

The **incidence angle**, i^* , is computed using:

$$\begin{split} \mathcal{K}_{t,i} &= \left(10 \ \frac{t_b}{c}\right)^q \text{; where } q = \frac{0.28}{0.1 + \left(\frac{t_b}{c}\right)^{0.3}} \\ (i_0^*)_{10} &= \frac{\beta_0^p}{5 + 46 \cdot e^{-2.3\sigma}} - 0.1 \ \sigma^3 \ e^{\frac{\beta_0 - 70}{4}} \text{; where } p = 0.914 + \frac{\sigma^3}{160} \\ n &= 0.025\sigma - 0.06 - \frac{\left(\frac{\beta_0}{90}\right)^{1 + 1.2\sigma}}{1.5 + 0.43\sigma} \\ i^* &= \mathcal{K}_{sh} \ \mathcal{K}_{t,i} \ (i_0^*)_{10} + n \ \theta \end{split}$$

The **deviation angle**, δ , is computed using:

$$K_{t,\delta} = 6.25 \frac{t_b}{c} + 37.5 \left(\frac{t_b}{c}\right)^2$$

$$(\delta_0^*)_{10} = 0.01 \sigma \beta_0 + (0.74 \sigma^{1.9} + 3\sigma) \left(\frac{\beta_0}{90}\right)^{1.67 + 1.09\sigma}$$

$$b = 0.9625 - 0.17 \frac{\beta_0}{100} - 0.85 \left(\frac{\beta_0}{100}\right)^3$$

$$m=rac{m_{1.0}}{\sigma^b}$$
 ; where $m_{1.0}=0.17-0.0333rac{eta_0}{100}+0.333igg(rac{eta_0}{100}igg)^2$

$$\delta = K_{sh} K_{t,\delta} (\delta_0^*)_{10} + m \theta$$

POLITECNICO MILANO 1863

Antonio Pucciarelli

Politecnico di Milano

Starting from the **known** flow deflection angle¹⁹, ε , it is necessary to compute:

$$\theta = \varepsilon - i^* + \delta$$

Since i^* and δ are functions of θ , the computation of θ is made by an iterative process:

$$\theta = \varepsilon - i_{(\theta)}^* + \delta_{(\theta)}$$

Once found θ , the **total pressure loss** coefficients, $\bar{\omega}_*$, are computed.

Politecnico di Milano

 Losses modeling
 Blade shape
 Radial equilibrium
- 4 turboLIB & Results

The **radial equilibrium** equation: $\frac{\partial h_t}{\partial r} = T \frac{\partial s}{\partial r} + V_a \frac{\partial V_a}{\partial r} + V_t \frac{\partial r V_t}{\partial r}$ is converted into, for the exit station²⁰ of the blade, a **1st order ODE**:

$$\begin{split} -\frac{1}{2}\frac{\partial V_{a2}^2}{\partial r} + \frac{V_{a2}^2}{2\frac{\partial s_2}{c_P}}\frac{\partial s_2}{\partial r} &= -c_P\frac{\partial T_{T1}}{\partial r} - \omega \; \frac{\partial rV_{t2}}{\partial r} + \omega \; \frac{\partial rV_{t1}}{\partial r} \\ + T_{T1}\; \frac{\partial s_2}{\partial r} + \frac{\omega}{c_P}rV_{t2}\; \frac{\partial s_2}{\partial r} - \frac{\omega}{c_P}rV_{t1}\frac{\partial s_2}{\partial r} - \frac{1}{2\frac{c_P}{c_P}}V_{t2}^2\frac{\partial s_2}{\partial r} + \frac{V_{t2}}{r}\frac{\partial rV_{t2}}{\partial r} \end{split}$$

- The **ODE** will be solved for V_{a2}^2
- s_2 is computed from $\sum_i \bar{\omega}_i$
- ω , V_{t1} , V_{t2} and T_{T1} are known

POLITECNICO MILANO 1863

²⁰1 is the blade inlet station and 2 is the blade outlet section.

 $^{^{21}\}bar{\omega}_{*}$ computation has been treated earlier in Losses modeling.

From pressure loss coefficients it is possible compute the **outlet total pressure** as:

$$P_{T2,r} = P_{T1,r} + \sum_{i} \bar{\omega}_{i} (P_{T1,r} - P_{1,r})$$

The **entropy variation** is computed as:

$$\Delta s = s_2 - s_1 = c_P \log \frac{T_{T2,r}}{T_{T1,r}} - R \log \frac{P_{T2,r}}{P_{T1,r}}$$

Frames

- $T_{T2} = T_{T1}$ in stators and $T_{T2,r} = T_{T1,r}$ in rotors
- $\bar{\omega}_*$ have to be computed using **relative** quantities for **rotors** and **absolute** quantities for **stators**

•
$$T_{T,r} = T + \frac{W^2}{2c_P} = T_T + \frac{W^2 - V^2}{2c_P}$$

•
$$P_{T,r} = P_T \left(\frac{T_{T,r}}{T_T}\right)^{\frac{\gamma}{\gamma-1}}$$

Blade number

In order to define a proper number of blades for the rotor and the stator, Howell's relations have been used for the estimation of the losses. These relations, [Aun04, Ch. 6], are:

- $\bar{\omega}_{profile+secondary}$, this is a relation that takes into account profile and 3D losses
- $\bar{\omega}_{endWall}$, this is previous expalined **end wall** loss

The NISRE is solved through a **double nested** loop:

- continuity loop. Inside the continuity loop the scipy.integrate.odeint function is used for the solution of the V_{a2}^2 ODE
- entropy loop. Inside the entropy loop the scipy.optimize.minimize function is used for the computation of the blade shape

At the end of the NISRE, all the main blade quantities are avaliable for the **generation** of the **3D geometry**. This geometry can be converted into a .stl file that can be used in OpenFOAM for the flow properties study. In addition a .scad file is made for understanding position and checking possible contacts between rotor and stator blades.

[Bas06] suggested that a good distance between rotor and stator blades is half of the rotor chord²².

²²In the radial equilibrium study losses between rotor and stator blades are **neglected**.
